No GPU? Train in the cloud

Source: `vignettes/articles/cloud-gpu.Rmd`

Google Colab has been tested end to end with this workflow (a free T4 trains the example in about four minutes). Kaggle, Lightning AI, and RunPod use the same notebook.

The run directory is the whole contract between R and the trainer, so a run can be trained on any machine with a GPU and its results copied back. `dragon_bundle()` zips the run, `dragon_remote()` opens a provider with the dragon-farm notebook and prints the steps, and `dragon_import()` puts the trained adapter into place. Nothing else changes: `dragon_generate()` and `dragon_merge()` work on the imported run as if it had trained locally.

```
run <- dragon_dataset(dragon_example_data()) |>
  dragon_map(prompt = "{subject}\n\n{body}", response = "rep
  dragon_bundle("Qwen/Qwen2.5-0.5B-Instruct")

dragon_remote(run, "colab")   # opens Colab with the noteboo
# ... upload the zip it names, Run all, download dragonfarm-
dragon_import(run, "~/Downloads/dragonfarm-results-<id>.zip"
```

Provider	Cost	What the link opens
Google Colab	Free tier with a T4; paid tiers for longer sessions	The notebook, directly
Kaggle	Free: about 30 GPU hours a week (T4 ×2 or P100)	The notebook, directly
Lightning AI	Free monthly credits, then pay as you go	The dragon-farm repo in a new Studio

RunPod	Pay per hour, wide choice of GPUs	The RunPod console

The app has the same path: the Train panel’s “No GPU here?” section prepares the bundle and gives you the download and the provider link, and the Monitor panel imports the results zip. `dragon_check()` points here when it finds no GPU, and a run that failed locally for lack of memory can be sent to the cloud as is with `dragon_remote(run, ...)`.
